##
      1948
              1970
                      1984
                              1983
                                      1998
                                               2012
```

For the sake of simplicity, we will only look at presidential elections since 1996.

As we can see, the sample size in 2012 is much bigger than it was in previous years. This is because in 2012, the ANES started doing some of their polling online, which allowed them to survey significantly more people. We will later explore the data in order to determine whether the responses of individuals who were surveyed online significantly differs from the responses of those who were surveyed over the phone or in person.

```
plot(as.factor(anes.data$year[anes.data$year >= 1996]), main = 'Sample Size by Year')
```

Sample Size by Year

```
#Only include years of interest
anes.data = anes.data[anes.data$year == 1996 | anes.data$year == 2000 | anes.data$year == 2004 |
                      anes.data$year == 2008 | anes.data$year == 2012, ]
#A much easier way to write that
anes.data = anes.data[anes.data$year %in% seq(1996, 2012, 4),]
summary(anes.data$year)
      Min. 1st Qu. Median
                              Mean 3rd Qu.
                                              Max.
##
      1996

              2000
                              2007
                                      2012
                                              2012
##
```

```
#Number of NAs
sum(is.na(anes.data))
## [1] 7729302
```

There are over 7 million NAs, but there are even more missing values since not all missing values are coded as NA, so we'll definitely have to do some data cleaning.

```

```

Age is coded as a factor variable, but in order to convert it to numeric, we need to first convert it to a character. This is because factor variables have

a built-in numeric value based on what order the levels are in. As a result, 17 would be converted to a 1, 18 to a 2, 19 to a 3, etc.

Also, we will recode missing values as NA since that is how missing values should be represented in R. Note that DK stands for 'Don't Know', RF means that they refused to respond.

```

```

Remember that each level of a factor variable is also stored as an integer. So instead of typing out the name of the level e.g. '0. DK; NA; no Pre IW; short-form 'new' Cross Section', you can simply refer to the integer that the level corresponds to. For example:

```
data$educ[as.numeric(data$educ) == 1] <- NA
```

Although it is easier to type, it is not as clear to the reader what exactly is being done.

1. 0 to 16 percentile

2. 17 to 33 percentile

Also, there does not appear to be a clear, systematic way to recode these values as NA since sometimes they are not constently labled.

```

Number of children is coded as a categorical variable instead of a numeric one. One way to convert this into a numeric variable would be:

```
#data$num.children2[data$num.children == 'O. None'] <- O
#data$num.children2[data$num.children == '1. One'] <- 1
#data$num.children2[data$num.children == '2. Two'] <- 2
#data$num.children2[data$num.children == '3. Three'] <- 3
However, since each level of a factor variable is stored as an integer, a much easier way to do this would be:
data$num.children = as.numeric(data$num.children) - 1
data$num.children[data$num.children == 9] <- NA
summary(data$num.children) #Looks good!
                                                        NA's
      Min. 1st Qu. Median
                               Mean 3rd Qu.
                                                Max.
